

Radon Mitigation System

Outdoor Installation

Applicability:

Active soil depressurization (ASD) is recognized by the U.S. Environmental Protection Agency, consumer groups, and scientific organizations as the most effective technique for reducing radon levels in homes and other buildings.

Principle of Operation:

A negative pressure field is created below the building to prevent the entry of radon gas.

Method:

One or more penetrations are made in the concrete floor (slab) and a small pit is created beneath each penetration. If there is no slab, a radon retardant vapor barrier is affixed over rock and dirt prior to creating the penetration(s). PVC vent pipe is connected to the penetration(s) and is typically routed unobtrusively to the suction side of the RadonAway radon mitigation fan. Additional PVC vent pipe is then connected to the pressure side of the fan and routed up the sidewall of the house to discharge the radon gas safely above the roof. A weatherproof electrical connection is provided for the fan.

Radon is an invisible, odorless gas that is a natural radioactive decay product of uranium, a common element in soil and rocks. Radon gas is considered harmless when dispersed in outdoor air but can be a serious health hazard when trapped in buildings.

Eagle received an **A+** Rating from the BBB!
